History of Antimatter

In 1928, Paul Dirac theorized possibility of antimatter as one of his equations for quantum mechanics had two “solutions” (regular matter and antimatter)

In 1932, Carl Anderson discovered positrons while studying cosmic rays

Two teams working at the Bevatron in Lawrence Berkeley National Lab discovered antiprotons and antineutrons in 1955 and 1956

In 1965, Antoni Zichichi of CERN and Leon Lederman of Brookhaven National Lab simultaneously discovered antideuteron

In 1995, CERN created antihydrogen atoms at the LEAR by slowing the antiprotons and attaching positrons

What is Antimatter?

Antimatter

“Those who say that antihydrogen is antimatter should realize that we are not made of hydrogen and we drink water, not liquid hydrogen”

-- Dirac

*Quoted from A. Zichichi (2008)
Antiparticles and antimatter:
the basic difference*

1. Annihilate with normal matter
 π^+, π^- are each other's antiparticle
2. Nuclear force
3. Relatively long lifetime

What are Hypernuclei ?

Nucleus which contains at least one hyperon in addition to nucleons.

Hypernuclei of lowest A

The first hypernucleus was discovered by Danysz and Pniewski in 1952. It was formed in a cosmic ray interaction in a balloon-flown emulsion plate.

M. Danysz and J. Pniewski, Phil. Mag. 44 (1953) 348

No one has ever observed **any** antihypernucleus before RHIC

- Y-N interaction: a good window to understand the baryon potential
- Binding energy and lifetime are very sensitive to Y-N interactions
- Hypertriton: $\Delta B = 130 \pm 50$ KeV; $r \sim 10$ fm
- Production rate via coalescence at RHIC depends on overlapping wave functions of $n+p+\Lambda$ in final state
- Important first step for searching for other exotic hypernuclei (double- Λ)

3-D Chart of Nuclides

Relativistic Heavy Ion Collider (RHIC)

Animation M. Lisa

Little Big Bang

BIG; All 4 forces at work; Gravitation dominates; QGP@ 10^{-6} s; Slow expansion; Antimatter-matter annihilate

Little; Strong force at work; QGP@ 10^{-23} s; Fast expansion; Antimatter-matter decouple; repeat trillion times

Can we observe hypernuclei at RHIC?

◆ Low energy and cosmic ray experiments (wikipedia):

hypernucleus **production** via

- Λ or K capture by nuclei
- the direct strangeness exchange reaction

hypernuclei **observed**

- energetic but delayed decay,
- measure momentum of the K and π mesons

◆ In high energy heavy-ion collisions:

- nucleus production by coalescence, characterized by **penalty factor**. 聚并
- AGS data^[1] indicated that hypernucleus production will be further suppressed.
- What's the case at RHIC?

Nuclear Experiment

Observation of the anti

STAR Collaboration

(Submitted on 16 Mar 2011 (v1), last revised 2

High-energy nuclear collisions create an antimatter are formed with comparable quickly from matter, and avoid annihilat antimatter. The antimatter helium-4 nucleus consists of two antiprotons and two antineutrons (baryon number $B=-4$). It is present in cosmic radiation at the accelerators, where the rate of antinucleus production in high-energy collisions decreases by a factor of about 1,000 with each additional antinucleon^{3, 4, 5}. Here we report the observation of the antimatter STAR experiment at RHIC in 10⁹ recorded gold-on-gold (Au+Au) collisions at centre-of-mass energies of 200 GeV and 62 GeV per nucleon–nucleon pair. The yield is consistent with expectations from thermodynamic⁷ and coalescent nucleosynthesis⁸ models, providing an indication of the production rate of even heavier antimatter nuclei and a benchmark for possible future observations of $^4\overline{\text{He}}$ in cosmic radiation.

Observation of the antimatter helium-4 nucleus

The STAR Collaboration

Affiliations | Contributions

Nature (2011) | doi:10.1038/nature10079

Received 14 March 2011 | Accepted 04 April 2011 | Published online 24 April 2011

High-energy nuclear collisions create an energy density similar to that of the Universe microseconds after the Big Bang¹; in both cases, matter and antimatter are formed with comparable abundance. However, the relatively short-lived expansion in nuclear collisions allows antimatter to decouple quickly from matter, and avoid annihilation. Thus, a high-energy accelerator of heavy nuclei provides an efficient means of producing and studying antimatter. The antimatter helium-4 nucleus ($^4\overline{\text{He}}$), also known as the anti- α ($\overline{\alpha}$), consists of two antiprotons and two antineutrons (baryon number $B = -4$). It has not been observed previously, although the α -particle was identified a century ago by Rutherford and is present in cosmic radiation at the ten per cent level². Antimatter nuclei with $B < -1$ have been observed only as rare products of interactions at particle accelerators, where the rate of antinucleus production in high-energy collisions decreases by a factor of about 1,000 with each additional antinucleon^{3, 4, 5}. Here we report the observation of $^4\overline{\text{He}}$, the heaviest observed antinucleus to date. In total, 18 $^4\overline{\text{He}}$ counts were detected at the STAR experiment at the Relativistic Heavy Ion Collider (RHIC; ref. 6) in 10^9 recorded gold-on-gold (Au+Au) collisions at centre-of-mass energies of 200 GeV and 62 GeV per nucleon–nucleon pair. The yield is consistent with expectations from thermodynamic⁷ and coalescent nucleosynthesis⁸ models, providing an indication of the production rate of even heavier antimatter nuclei and a benchmark for possible future observations of $^4\overline{\text{He}}$ in cosmic radiation.

Existence is no surprise

It's still unclear whether finding the antihypertriton will have practical implications for physics, said Frank Close, a physicist at the University of Oxford and author of the book *Antimatter*. "One way of saying it is it's **stamp collecting**. Some stamps are more exciting than others," he said. "The fact that this particle has been found **confirms our general belief** that antimatter should exist just as much as matter exists," Close added. --- February 2011, National Geographic

"It is an enormous technical achievement that they can extract these rarely produced objects," says Tom Cohen, a nuclear physicist at the University of Maryland, College Park. "But everybody believed—I should almost say knew—that anti-alpha particles could exist." Cohen compares the feat with climbing the world's tallest mountain: "It's really impressive that you can do it, but the fact that there's **a summit to Mount Everest is not a big surprise**."

"It's really, really very impressive that they're able to do that, to see these rare events and convincingly isolate them," he says. "What they've found is that **there is no shock**; it's where it's predicted to be."

"Some of my colleagues take it for granted that there obviously has to be an anti-alpha. My view, and I am a theorist, is that it **is just an idea** — of course a good idea - **until it is actually seen**. The fact that you encountered the antihypertriton - no one's obvious choice - on the way, is a sign that probing the attainable structure of antimatter is a real scientific adventure. "

Predictability is a shock

If I told you that:

1. create a state of matter at 4×10^{12} degrees out of a few thousands of particles
2. Matter and antimatter do not annihilate at energy density 100 times the normal nuclear density
3. Anti-nuclei and nuclei with weak binding energy carry information from the QGP phase transition (Temperature = 160MeV)
4. All particles maintain statistical equilibrium (no sign of annihilation but coalescence)
5. Models that assume thermal equilibrium correctly account for yields spanning 11 orders of magnitude.
(1000 π , 10^{-8} ^4He)
 ± 0.000000000001

How many of you would say that “I expect that!”?

That is what we did when we found all these Heavy antimatter nuclei!

Predictable Production Rate

Antimatter Galaxies

Seeing a mere antiproton or antielectron does not mean much— after all, these particles are byproducts of high-energy particle collisions. However, complex nuclei like **anti-helium** or anti-carbon are almost never created in collisions.

What happens if we replace antiproton
with **antideuteron, antitriton or antiHelium3**

Atomic structure should be the same
for antideuteron and antitriton (-1 charge)
Reduced mass M^* will be different.

Only RHIC can answer this question with
enough antimatter nuclei for such study

Possible Physics Topics:

- Measure antinucleus mass and magnetic moment for CPT test,
- Study the antinucleus annihilation process (sequence)
- antinucleus-nucleus Annihilation
(what do they create? Hot or cold matter)
- Maybe even antiAlpha Atomcule
